OBJECTIVE:
To investigate how sky limiting magnitude influences the visibility of hilal

HOW DO WE CONDUCT THE RESEARCH?
To conduct this research:
1. Choose west-facing sites – because the hilal sets at west. The sites are: 1) Telok Kemang, Malaysia; 2) Kuala Lumpur, Malaysia; and 3) Coonabarabran, Australia.
2. Measurements of the limiting magnitude were made at least one hour before and after the Moon set on dates spread over a period of six months.
3. The data were taken using Sky Quality Meter (SQM) which records the visual magnitudes per square arcsecond (mpsas) to measure sky limiting magnitude.

RESULT & CONCLUSION
Table 1 showed preliminary results of this research which is the limiting magnitude threshold for the hilal to be witnessed. The given readings implies that reading within that range, there is high possibility to witness the hilal. On the other hand, reading with less than 16 mpsas, the hilal was not visible during the observation.

The main important result of this research is to find out a vital parameter for hilal observations in order to increase its visibility – proposing a new criteria. This research helps us to understand the phenomenon better about the threshold of sky limiting magnitude for hilal.

7 QUICK FACTS
1. The origin to differentiate new moon and Islamic new moon is based on Quranic verse: “They ask you about the crescent moons; say they are a means to measure your specific times (mawaqit) and are also for the commencement of the hajj” (2: 189).
2. Malaysia opts to choose imkanur rukyah (lit. possible of visibility by observation) – one of method in determining new hijriic month (Islamic calendar).
3. Imkanur rukyah has three (3) criteria: 1) 2° of Moon’s altitude; 2) 3° of Moon-Sun elongation; and 3) minimum of eight (8) hours of Moon’s age.
4. The visibility of new moon is a function primarily of the angle between the moon, observer, and sun (which affects the brightness of the crescent) and the apparent altitude of the moon above the horizon and of the sun below the horizon (which affects the background brightness against which the moon is to be observed).
5. Based on hilal observation report (1972-2015) by JAKIM (Malaysia Department of Islamic Development), before 1990, the hilal was more frequently seen in 29th day. After 1990, the hilal was frequently seen in 30th day.
6. The culprit hilal visibility for many years is misdirected, excessive and obtrusive artificial light – light pollution.
7. This research proposing a new criteria for hilal observation i.e. Threshold of sky limiting magnitude.
